Computational fluid dynamic modeling can be a powerful tool in studying physical systems such as aneurysms, but extrapolating from idealized experimental systems to the in vivo state must be done carefully. All computational methods require the use of assumptions that are essentially shortcuts to predicting the more complicated natural state.

Pulmonary hypertension (PH) is a chronic progressive disease characterized by elevated pulmonary arterial pressure, caused by an increase in pulmonary arterial impedance. Computational fluid dynamics (CFD) can be used to identify metrics representative of the stage of PH disease. However, experimental validation of CFD models is often not pursued due to the geometric complexity of the model or ...
