Functional languages are more of math based. A purely functional concepts of programming languages I can remember of is Haskell. Another one is Scala, but it is not fully functional, but it can be made to work that way. Haskell, on the other hand, doesn't tend to work like other concepts of programming languages and it is based on pure logic.

The overloading is also another key concept of object oriented programming language. In one line, we can define overloading as it is the capability of a single function to perform different task depending on the situation. So, the concept of overloading is somehow related to the polymorphism property of OOP.

Many languages allow new static scopes to be defined in the midst of executable code. This powerful concept, allows a section of code to have its own local variables whose scope is minimized. A section of code is called a block. 1. Decide which of the following identifier names is valid in C language.
